Idiopathic Intracranial Hypertension- Clinical Spectrum- A Study Of Risk Factors, Clinical Profile And Management Outcomes

1DR. PRATHYUSHA T, 2DR. SRINIVAS. B
ASSISTANT PROFESSOR, POST GRADUATE
NRI MEDICAL COLLEGE

Abstract: Background –Benign Intracranial Hypertension is a syndrome defined by increased intracranial pressure, normal CSF composition, absence of ventriculomegaly and intracranial lesion. There are controversies regarding etiology, clinical features and treatment outcomes of BIH. Therefore, the aim of this study was to describe risk factors, clinical profile, treatment and in patients with Benign Intracranial Hypertension in a tertiary hospital. Methods: The study was done between August 2017 - August 2021. 33 cases of benign intracranial hypertension who are suspected by history, confirmed by MRI and MR Venography

Results: In this study most patients with this disease present in the third decade of life. [2], of which 22 members in between 18-40 yrs, 10 members in between 41-60 yrs, 1 member more than 60 yrs. IIH has a strong predilection for obese women, of which 24% is of < 25 kg/m², 42% is of 25-29 kg/m² and 22% is of 30-35 kg/m², >35 kg/m² 12%. The most common presentation is vomiting in 45%, headache in 42% [3] Other symptoms include visual disturbances, lateral rectus palsies in 12% cases, CSF rhinorrhea in 18% 94% patients responded to medical management of which 24% to repeated lumbar punctures, 39% to LP PLUS Diuretics, 31% to LP plus diuretics plus steroids. If persistent headache with rapidly deteriorating visual disturbances were present surgical management in 6% was advised

Conclusion: Early diagnosis and application of diuretics or corticosteroids most often guarantee the successful control over clinical symptoms and papilledema

KEYWORDS: PAPILLOEDEMA, LUMBAR PUNCTURE, STEROIDS, OBESITY.

INTRODUCTION
- Benign Intracranial Hypertension is a syndrome defined by increased intracranial pressure, normal CSF composition, absence of ventriculomegaly and intracranial lesion[1]
- Also known as Pseudotumor Cerebri and Idiopathic Intracranial Hypertension
- Etiology of BIH remains uncertain in majority of patients
- But there is an association of BIH with several risk factors.
- Young, obese or recent weight gain females of reproductive age has been found to have strong association with BIH hypoparathyroidism [2].
- Other risk factors include Drugs like tetracycline, risperidone vitamin A, E and steroid overuse some endocrine & Metabolic dysfunctions like adrenal insufficiency, cushings, hypothyroisim hypoparathyroidism [2]
- Most common symptom of BIH includes
  • headache,
  • nausea, vomiting,
  • dizziness,
  • transient visual obscurations like lateral rectal palsy,
  • ocessasionally CSF rhinorrhea
  • tinnitus[3,4,5]
- Most common sign of BIH includes papilledema in majority of cases and CSF opening pressure was more than 20 cm of H2O with normal CSF composition
- Methods of treatment include
  • weight loss,
  • withdrawal of associated medication,
  • acetazolamide or furosemide therapy, [6]
  • systemic corticosteroids,
  • repeated lumbar punctures,
  • surgical decompression
- Outcome of treatment is assessed by regression of papilledema and resolution of symptoms.
- There are controversies regarding etiology, clinical features and treatment outcomes of BIH.
Therefore, the aim of this study was to describe risk factors, clinical profile, treatment and in patients with Benign Intracranial Hypertension in a tertiary hospital.

Methods and materials
- The study was done between August 2017 - August 2021.
- 33 cases of benign intracranial hypertension who are suspected by history, confirmed by MRI and MR Venography
- The following data were used from the clinical records:
  - Sex,
  - Age,
  - Risk factors like BMI
  - Clinical presentation
  - Imaging methods (CT scan, MRI, and MR angiography).

Treatment (lumbar puncture, acetazolamide, surgical management)

Benign intracranial is diagnosed if patient meets following criteria

Modified Dandy Criteria (2001) Diagnostic criteria:[10]
1. Signs and symptoms of increased intracranial pressure
2. Awake and alert patient.
3. No abnormal neurological findings except papilledema or abducens nerve (CN VI) palsy [3,4]
4. Normal CT/MRI except for empty sella or small ventricles [8]
5. Increased CSF opening pressure
   - (>20 cm H 2 O in nonobese or
   - >25 cm H 2 O in obese patient)
   - with normal CSF composition
5. No other known cause of raised intracranial pressure

Results
- Mean age at time of admission was 34.6 years (range 18-63yrs). Incidence is more in middle aged groups
- The group included 31 women and 2 men. Incidence is more in women compared to men.
- Considering Risk factors, obese people has more incidence compared to non obese people.

Discussion

- The main limitation of this study is lack of generalizability due to its retrospective nature.
- Incidence of IIH ranges from 0.9 to 1.0 per 100,000 in the general population, increasing to 1.6-3.5 per 100,000 in women and to 7.9-20 per 100,000 in women who are overweight[^6,7].
- Although IIH may affect individuals of any age, in this study most patients with this disease present in the third decade of life[^8], of which 22 members in between 18-40 yrs, 10 members in between 41-60 yrs, 1 member >60yrs compared to study by Alexandra Tzoukeva et al[^7].
- In this study, IIH has a strong predilection for obese women, Of which 22% is of <25kg/m2, 45% is of 25-29kg/m2 and 22% is of 30-35kg/m2. More than 90% of patients with IIH are obese women of childbearing, this is comparable to study by Hannerz J et al[^5,6].
- There are many such rare ‘associations’ but some of these include:
  - Taking (or after stopping) certain medicines such as steroids, some antibiotics and oral contraceptive pills
  - Other diseases such as SLE, Sarcoidosis and kidney diseases.
  - Pregnancy
- According to study and literature, the most common presentation is vomiting in 45%, headache in 42%.[^3] Other symptoms include visual disturbances, lateral rectus palsies in 12% cases, CSF rhinorrhea in 18% compared to study by Friedman DI et al[^8].
- Most common sign in BIH is papilloedema in fundus examination[^11].
- Imaging of patient shows no thrombosis but fulfilling criteria for BIH. Lumbar puncture was performed in this patients showing increased CSF opening pressure (>20 cm H 2 O in non-obese or >25 cm H 2 O in obese patient) as by Friedman DI et al[^11].
- CSF analysis was normal
- Visual field charting was performed in all patients to known the extend of visual loss.

- Various treatment modalities includes[^6,9]
  1. Weight reduction and cessation of offending drugs
  2. Repeated lumbar punctures
  3. Adding acetazolamide or furosemide if symptoms persists compared by study done by Celebisoy N[^9]
  4. Adding systemic steroids
  5. Surgical decompression if medical management fails[^15]
- 94% patients responded to medical management of which 24% to repeated lumbar punctures, 39% to LP PLUS Diuretics, 31% to LP plus diuretics plus steroids.
- If persistent headache with rapidly deteriorating visual disturbances were present surgical management in 6% was advised compared to study by Ball AK et al[^15].

Conclusion

- Our study suggests that BIH is most commonly associated with young age, female sex, and obesity.
- Neuro ophthalmologic examination, neuroimaging, and CSF evaluation are the most useful diagnostic tools.
- Early diagnosis and application of diuretics or corticosteroids most often guarantee the successful control over clinical symptoms and papilledema.
